Assignment 8

General information

- The recommended tool in this course is R (with the IDE R-Studio). You can download R **here** and R-Studio **here**. There are tons of tutorials, videos and introductions to R and R-Studio online. You can find some initial hints from **RStudio Education pages**.

- When working with R, we recommend writing the report using R markdown and the provided **R markdown template**. The remplate includes the formatting instructions and how to include code and figures.

- Instead of R markdown, you can use other software to make the PDF report, but the the same instructions for formatting should be used. These instructions are available also in **the PDF produced from the R markdown template**.

- We supply a Google Colab notebook that can also be used for the assignments. We have included installation of all nessecary R packages and hence this can be an alternative to using your own local computer. You can find the notebook **here**. You can also open the notebook in Colab **here**.

- Report all results in a single and *anonymous* pdf.

- The course has its own R package `bsda` with data and functionality to simplify coding. To install the package just run the following (upgrade="never" skips question about updating other packages):

  1. `install.packages("remotes")`
  2. `remotes::install_github("MansMeg/BSDA",`
     `subdir = "rpackage", upgrade="never")`

- Many of the exercises can be checked automatically using the R package `markmyassignment`. Information on how to install and use the package can be found **here**. There is no need to include `markmyassignment` results in the report.

- Common questions and answers regarding installation and technical problems can be found in Frequently Asked Questions (FAQ).

- Deadlines and information on how to turn in the assignments can be found in Studium.

- You are allowed to discuss assignments with your friends, but it is not allowed to copy solutions directly from other students or from internet. Try to solve the actual assignment problems with your own code and explanations. Do not share your answers publicly. Do not copy answers from the internet or from previous years. We compare the answers with urkund. All suspected plagiarism will be reported and investigated.

- If you have any suggestions or improvements to the course material, please post in the course chat feedback channel, create an issue, or submit a pull request to the public repository **here**

Information on this assignment

This assignment is related to Chapter 7.

Note! This assignment build upon assignment 7, so be sure that assignment 7 is correct before you start with this assignment. You can ask TAs for help to check that your assignment 7 answer is good.

Reading instructions: Chapter 7 in BDA3, see reading instructions. The ['loo' package vignette on the basics of LOO](https://mc-stan.org/loo/articles/loo2-with-rstan.html) shows an example of how to modify Stan code and use the package with Stan models. Also read about the PSIS-LOO that in **this article** or **the corresponding preprint**.

Reporting accuracy: For posterior statistics of interest, only report digits for which the Monte Carlo standard error (MCSE) is zero. *Example:* If you estimate $E(\mu) = 1.234$ with $\mathrm{MCSE}(E(\mu)) = 0.01$, you should report $E(\mu) = 1.2$.

Installing and using `stan`: To install Stan on your laptop, `https://github.com/stan-dev/rstan/wiki/RStan-Getting-Started`. If you encounter problems, see additional answers in the **FAQ**. Recently there have been reports of installation problems with Windows and R 4.0 (see Stan discourse for more).

Installing and using `CmdStanR`: If you want to use Stan in R on local computer, it can be easier to install CmdStanR interface mc-stan.org/cmdstanr/.

Additional useful packages are `loo`, `bayesplot` and `shinystan` (but you don't need these in this assignment). For Python users, `PyStan`, `CmdStanPy`, and `Arviz` packages are useful.

Stan manual can be found at `https://mc-stan.org/users/documentation/`. From this website, you can also find a lot of other useful material about Stan.

Model assessment: LOO-CV for factory data with Stan

Use leave-one-out cross-validation (LOO-CV) to assess the predictive performance of the pooled, separate and hierarchical Gaussian models for the factory dataset (see the second exercise in Assignment 7). To read in the data, just use:

```
library(bsda)
data("factory")
```

PSIS-LOO is a recently developed method for approximating the exact LOO and is thus not in BDA3. For more information, see the original paper **here** or **here**.

Use Stan for fitting the models, and the `loo` R package for computing the approximate LOO-CV given the posterior samples provided by Stan. You can install the package as

```
install.packages("loo")
```

Python users can use PSIS-LOO implementation in ArviZ library.

The report should include the following parts.

1. Fit the models with Stan as instructed in Assignment 7. To use the `loo` or `psisloo` functions, you need to compute the log-likelihood values of each observation for every posterior draw (i.e. an S-by-N matrix, where S is the number of posterior draws and $N = 30$ is the total number of observations). This can be done in the `generated quantities` block in the Stan code.

2. Compute the PSIS-LOO elpd values and the $\hat{k}$-values for each of the three models. **Hint!** It will be convenient to visualize the $\hat{k}$-values for each model so that you can easily see how many of these values fall in the range $\hat{k} > 0.7$ to assess the reliability of the PSIS-LOO estimate for each model. You can read more about the theoretical guarantees for the accuracy of the estimate depending on $\hat{k}$ from the original article (see **here** or **here**), but regarding this assignment, it suffices to understand that if all the $\hat{k}$-values are $\hat{k} \lesssim 0.7$, the PSIS-LOO estimate can be considered to be reliable, otherwise there is a concern that it may be biased (too optimistic, overestimating the predictive accuracy of the model).

3. Compute the effective number of parameters p_{eff} for each of the three models. **Hint!** The estimated effective number of parameters in the model can be computed from equation (7.15) in the book, where $\text{elpd}_{\text{loo-cv}}$ is the PSIS-LOO value (sum of the LOO log densities) and lpd is given by equation (7.5) in the book.

4. Assess how reliable the PSIS-LOO estimates are for the three models based on the $\hat{k}$-values.

5. An assessment of whether there are differences between the models with regard to the $\text{elpd}_{\text{loo-cv}}$, and if so, which model should be selected according to PSIS-LOO.

6. Both the Stan and R code should be included in your report.
